Abstract: Agriculture in Iran is the greatest economical sector after petroleum and services sectors which has devoted about 20 percent of national gross production and main share of non-petroleum exports, so that, this section development has determinate role in economical growth. Investment in agriculture section is one of factors which due to increase in demand for food and other agriculture products can cause to develop production and more employment in agriculture section. Therefore, in this section, it has been tried that Long-term effect of parameters such as petroleum incomes, investment stock, value-added, national income and inflation rate on state or governmental investment by use of conditional ARDL pattern is in frame of Pesaran and Shin (It applies for time series and variables can be I (0) or I (1)), this is studied for 1356-1386 periods. The results of this study showed that there is Long-term relation between governmental investment, petroleum incomes, investment stock, value-added, national income and inflation rate. On the other hand, governmental investment has the most and least sensitive to Value-added and petroleum income, respectively.

Key words: Governmental investment, ARDL model, error correction model, elasticity.

INTRODUCTION

Agriculture section is one of the most important sections in Iran economy. It is done about one-quarter of gross domestic production and foreign exchange incomes resulting from non-petroleum goods exports and country employment and to meet needs about 80 percent of society food needs via this section on one hand, it is created evolution in this section about high population growth, continuous increase in food demand and increasingly need in various economical section to agriculture products, so that it can increase in quantity and variety of different products in short time (Hazhbar kiani & Jhonvislo 1379). In addition, 43% of country population live in village, so the living of many of them is related to this section. Hence, agriculture section is considered as development axis (Kiani rad & Koopahi 1379). Generally, among investment in agriculture section has important role and specific place. The investment in agriculture section, due to increase in demand for food and other agriculture products, can cause to develop production and employment. In fact, increase in demand cause to enhance prices levels and increasing price levels cause to enhance motive for investing. Therefore, more investment is accompanied by production growth and more employment. Besides, prior and post relation of agriculture with other parts helps to develop production and employment in them. Most of agriculture activities are done in rural regions, thus investment development in agriculture section in frame of public and private investment can cause to create more occupational opportunity in rural regions, as a result it causes to prevent rural-people immigration to cities and increase in growth rate at agriculture section (Amini & Falihi 1377). On one hand, the study of changes trend in production and imports at agriculture section clear this fact which by existing increase in main agriculture products manufacture, it is also provided main share of agriculture products by imports. It is necessary to pay attention to agriculture section via the study of agriculture section share from total value-added and human resource employment and its comparison with investment share in this section of whole investment country. In respect to importance of agriculture section in economical growth and development and investment power to enhance agriculture products manufacture and to develop this section, the investment has typical importance in it (Hazhbar kiani & Jhonvislo 1379). In Iran, the subject of invest and investment is accompanied by tremendous problems because of server dependence to petroleum incomes and its price unstable and to be high risk, in this reason investment in various sections such as agriculture one has had server fluctuation. In agriculture section, the problems related to investment have been more obvious due to existing structural bottlenecks and lack of financial equipments of most beneficiaries. In respect to this point that agriculture section has important role in domestic gross production and employment and it
The study of public investment procedure in agriculture section and its transgression challenges.

Table 1 shows investment rate of governmental section in agriculture section, each section share and growth rate from 1376 to 1386 by fixed prices in 1376.

The challenges in the agricultural sector investments include:
1- To be low rate of capital revenue in agriculture section which it is resulted in decrease in investment trend in this section in respect to keep low agriculture products prices.
2- Lack of foreign exchange and rial credits to form capital in this section.
3- Not to be provided financial, economical and technical equipments to attract foreign investment.
4- Lack of investment and essential financial resources to create and extend conversional industries and technical units.
5- Not to be recognized reforming instruments and conducting government to conduct private section resources and bank regime in direction of production investment and lack of it’s continuous.

6- Lack of encouragement regime for private section partnership and to commerce production in agriculture section.
7- Lack of supportive elements such as investment insurance in agriculture section.

Review on studies:
Bagheri & Torkamani (1379) have studied situation and relation between private and public investment in agriculture sector using coaggregation test. The results of estimation for this study private investment showed that state investment, bank credits, prices index and state investment with one pause over private investment is effective and also there is one long-term balance relation between function variables by use of coaggregation test and the important result of this study is the positive effect of state investment on private investment. Salimi far & Ghavi (1381) showed that there is significant relation between effect of granted credits of bank net on private section investment by estimate private section investment pattern as function of public section investment, domestic gross production, loans and grant credits of bank net.

Khaleidi et al (1387) studied the effective elements on rural poverty and agriculture economy growth with emphasis to agriculture section investment by use of statistic in period of 1350-1382 and via seemingly unrelated equations (SURE). The result of this study showed that although investment in agriculture section has been accompanied by economical growth in this part; but, it has not been superficial the rate and distribution of revenue resulting from this growth. It is seemed that agriculture economical growth revenue is not...
directed towards the rural poor people. Hence, in addition to control inflation rate and to improve revenue distribution resulting from economical growth of agriculture section, it must be noticed capital injection to agriculture section in order to support the poor people as typical in policies of investment development in this section.

Yousefi & Aziz nejad (1388) have studied the effect of domestic gross production variables, state investment, inflation rate and role of organizations such as security, ownership rights, rules and regulations, official invalidity and social security on Iran private investment during 1363-1383 years. The results showed that while domestic gross production and substructures have had positive effect on private investment, but the most important inhibition of private investment in Iran has been related to law and rights problems, lack of investment security, ownership rights and invalidity.

Ghali (2000) has studied the relation among private and public investment by method of error correction and they have concluded that in long-term, public investment has negative effect on private investment and economical growth, but in short-term it has negative or no effect on private investment and growth respectively.

Emran et al (2003) have studied the effect of economical freedom on private investment in India via estimation of investment function as method of self-regression (ARDL). The results showed that there is positive and significant relation between freedom and private investment.

Petrick (2004) has analyzed state credits about farmers investment behaviour including credit ration in Netherlands, this analysis was done by help of information economic evaluation analysis resulting from farmers families, in statistical analysis, it was determined that borrower reputation is not only prepare rent land but also the effect of ration which has credit. The estimation of one investment equation showed that access to subsidization has important role in determine farmers’ investment behaviour statistically; in various features, the relation of credits ration about margin credit effect on investment was less than one. This demonstrates that credit is sometimes used as something except production investment. Besides, investment volume has reverse relation with agriculture land size. Governmental policies, which are used to promote production investment and efficiency, must emphasize to grant loan as high amounts without discrimination about small lands.

Mizutani & Tanaka (2005) have studied the effect of public substructure on private section production and effect of economical policies on investment in public substructures. Their used information in this research is panel data related to 46 departmental domains in Japan in 1975, 80, 85, 90 & 95 years. They have applied coincident equations system consisted of private section production function, function to form public capital, governmental public investment function and regional public investment function. In this research, public capital is defined as sum of capital stock in transportation, seaport and airport, agriculture and national security sections. The results of these research shows that public capitals have effect on production efficiency in private section, and there is one complementary relation between regional or local and national governments investments. Political elements are not so effective on governmental investments in public section and national government supports to create public substructure result in local governments’ investment.

Research Method

In order to study existence of long-time relation and to obtain this relation for governmental investing in Iran agriculture section during 1356-1386 periods, it has been used the usage of unrestricted error correction model (ARDL) given by Pesaran and Sheen (1995).

They (1999) showed that ARDL pattern give consistence estimations from long-time coefficient which are normal as the asymptotic and regressors can be I(0) or I(1). Also Inder (1993) showed that these patterns are useful for small samples (limited) and alternatively it is suggested that unrestricted error correction model (UECM) enters dynamic to estimate of short and long time coefficients. Pesaran (1997) and Inder (1993) separately showed that to enter dynamic may correct regressors in ARDL and UECM. At last, it is prevented to create false regressions and unreliable estimations (Ghorbani et al 1386).

As mentioned, the main advantage of Pesaran & Shin method is that pattern variables can be I(0) or I(1); it means that there is no longer need to be I(1) for all pattern variables. Besides, this pattern isn’t suitable for small samples. So that Pesaran & Sheen (19995) divide ARDL approach in two stages.

In the first stage of convergence existence, we use F-test in order to study to be significant variables and then we use Pesaran & Sheen table (1996). We compare that statistic with two critical values. Its reason is that we must apply unit root test, because according to Evatera (2004), if pattern variables aren’t I(2), then F- statistic related to Pesaran & Sheen test doesn’t have credit because this test is done under this theory which these are variables of I(0) or I(1). Hence, it must be done unit root test about Pesaran & Sheen ARDL so that it is be sure
that none of pattern variable are if this statistic is larger than high critical value, then it will be accepted convergence and if this statistic is smaller than lower critical value, then it will be rejected convergence existence (Bahmani oskoyi 2002). Second stage includes estimation of equation and determination of estimate coefficient by use of ARDL method. First: we apply two zero hypothesis (there isn’t convergence state) and mutual hypothesis for convergence among variables.

\[ H_1 : \delta_1 \neq 0, \delta_2 \neq 0, \delta_3 \neq 0, \delta_4 \neq 0 \]
\[ H_0 : \delta_1 = \delta_2 = \delta_3 = \delta_4 = 0 \]
\[ H_1 : \theta_1 \neq 0, \theta_2 \neq 0, \theta_3 \neq 0, \theta_4 \neq 0 \]
\[ H_0 : \theta_1 = \theta_2 = \theta_3 = \theta_4 = 0 \]

Then it is tested hypothesis by obtaining statistic, and we decide. So in second stage, we apply ARDL method to estimate investment equation.

Second: there are four criteria to determine numbers of optimum pause which include: 1- Square criterion, 2- Akaike criterion (AIC), 3- Schwarz Bayesian (SBS) and 4- Hannan-Quinn criterion (HQIC). We choose one of these for criteria and estimate them by determine number of pauses. We basically try that there wouldn’t be serial correlation (there isn’t significant relation between disturbance components) in Diagnostic statistics (Static statistic); form of variance in identical function means that there are identical variances in various and different samples. To be normal suppose that disturbance components have normal distribution which we study it via error period and diagram and determine that are there above problems in data, as a result we solve them via different methods and finally we estimate real variables value (Bahmani oskoyi 2002).

ARDL method has been delivered by Pesaran et al (1996) to determine co-summation relation between variables. In this method, in spite of Yooohan son idea, it isn’t needed to know degree of variables co-summation in model. Meanwhile, it is also determined number of sum vectors. In this method, to study co-summation relation between Xt and Yt variables, his estimated two equation types. The equation, which is dependent to Xt variable, is as follow:

\[ \Delta Y_t = \alpha_2 + \sum_{i=1}^{k_2} b_{2i} \Delta X_{t-i} + \sum_{i=1}^{k_2} c_{2i} \Delta Y_{t-i} + \omega_2 X_{t-1} + \omega_2 Y_{t-1} + \epsilon_{2t} \]

Where, Y is dependent variable, X is dependent variable and \( \epsilon_2 \) is disturbance term. The coefficients of \( \alpha_2, b_{2i}, c_{2i}, \omega_2, \) and \( \epsilon_2 \) are estimation able parameters. The rest symbols have the same definition in relation (1).

In relation (1), Xt variable is dependent one, zero hypothesis is based on lack of long-term relation among variables.

We test \( H_0: \alpha_2 = \omega_2 = 0 \) against opposite hypothesis \( H_1: \alpha_2 \neq 0, \omega_2 \neq 0 \) by use of F-test which we call FX (xy). But distribution of this F statistic, regardless I(0) or I(1) or to be independent variables model, is not standard. In this reason, Pesaran et al (1996) have given suitable critical amounts in respect to independent variables in model and existence or lack of width from origin or time trend. These statistics include two complexes (column). One complex has been calculated by propose these variables I(0) and another one by propose I(1) for all variables. If calculated F-statistic exceed from upper limit of critical amounts domain given by Pesaran et al, then we will reject zero hypothesis based on lack of long-term relation between variables. In this state it can be deduced that there is one-way causality relation from Xt variable to Yt one. If calculated F-statistic is less than lower limit in this domain, then we couldn’t reject zero hypothesis and in this state, there isn’t causality relation between variables. If calculated F-statistic is located inside critical amounts domain, it will be deduced in certain result. This procedure must be repeated for another equation.

**Generalized Dicky-Fuller test:**

In this method, it is used first-degree differential terms with pause or auto-regression AR(p) to solve the correlation problem. The number of pauses are determined based on this point that disturbance term, \( \epsilon_t \) time series doesn’t have serial correlation. This test can be stated as follow:
\[ \Delta y_t = c + \beta_t + \alpha y_{t-1} + \sum_{i=1}^{\infty} \alpha_i \Delta y_{t-i} + u_t \quad u \sim iid (\alpha, \delta^2) \]

\[
H_0 : \alpha = 0 \\
H_1 : \alpha < 1
\]

In this test, \( H_0 \) hypothesis implies existence of unit root and opposite hypothesis shows series stand. Therefore, if calculated t-statistic absolute value is larger than critical absolute value, this means to reject \( H_0 \) hypothesis (existence of unit root). It is worth to point out that to select form (having time procedure and width from origin) and also suitable pause to test ADF in results are effective, so that increase in pause numbers will result in decrease test power; because, on one hand, it is increased the number of estimated parameters, and on the other hand, it is decreased the number of useful observation and therefore, Test power is also decreased by decrease in freedom degree.

Discussion and Conclusion:

It has been considered governmental investment pattern as follow general form:

\[
SIA = F(ROG, SI, VA, Y, P)
\]

SIA: Governmental investment in agriculture section
ROG: Petroleum incomes
SI: Capital stock with one pause in agriculture section
VA: Value-added
Y: National income
P: Inflation rate

It was used generalized Dicky-Fuller test to study governmental investment stability in agriculture section. It has been give ADF as it results in table (1). As table information show that all variables except petroleum incomes are in instability level and their first degree difference is stable. In another words, these variables of sum pattern is I(1) degree.

</tbody>
</table>

* Significant at 10% level, **Significant at 5% level, ***Significant 1% level
The result of table (3) show that governmental investment in long-term is effected by itself with one pause. In another words, one previous period investment has negative and significant effect on governmental investment. Petroleum income, national income and capital stock in long-term have positive effect on governmental investment and are meaningful or significant statistically. Value-added is in significant statistically, but has negative effect on governmental investment, inflation rate has also positive and significant effect on state investment in long-term, so that the agriculture section institutions have mostly subside, therefore increase in inflation on their price is not so effective so increase in price cause to increase in profit from investment in agriculture section and also motivation for investing.

Table (4): Results of the estimation elasticity’s

<table>
<thead>
<tr>
<th>Variables</th>
<th>Elasticity</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROG</td>
<td>0.82</td>
</tr>
<tr>
<td>SI</td>
<td>1.24</td>
</tr>
<tr>
<td>VA</td>
<td>1.73-</td>
</tr>
<tr>
<td>Y</td>
<td>1.32</td>
</tr>
<tr>
<td>P</td>
<td>1.19</td>
</tr>
</tbody>
</table>

Based on information in table (4) it is observed that strengths of variables in petroleum income, capital stock with on pause, national income and inflation rate equal to 0.82, 1.24, 1.32 and 1.19 respectively, assuming the other conditions constant, if the rate of these variable increase as one percent, then the rate of governmental investment increase as 0.82, 1.24, 1.32 and 1.19 respectively. Also governmental investment decrease in as amount of 1.73 by one percent increase in value-added, also the results of table show that governmental investment has the most sensitive relative to value-added, so that one percent increase in value-added causes to decrease in 1.73 percent in governmental investment.

It was used Ramsey’s reset test in order to study absent or present affirmation error, the results of test showed absent of affirmation error in pattern. Self-correlation test showed that there isn’t self-correlation disturbance between terms. It was used cumulative sum (CUSUM) and cumulative sum of squares (CUSUMSQ) Braven et al (1975) in order to study estimated parameters stability.

In this test, in spite of some tests such as Chaw, it is not necessary to determine structural break point. Diagram 1 and 2 showed the result of this test. There two diagrams show that estimated parameters in pattern are stable.

Estimation of long-term relation in public section investment by estimator of error correction model (ECM):

We enter long-term function the rest terms with one pause to short-term functions to study error correction model.

Governmental investment function short-term model in agriculture section is as follow:

\[
\Delta(SIA)_t = 0.01 + 0.51\Delta(ROG) + 0.06\Delta(SI) + 1.17\Delta(VA) + 0.19\Delta(Y) + 0.13\Delta(P) - 0.69ECM(-1)
\]

\[
T: (0.25) (4.27) (0.31) (1.66) (0.52) (0.42) (-3.46)
\]

\[
R^2 = 0.77
\]

\[
F = 13.25
\]

\[
D.W = 2.00
\]

\[
\bar{R}^2 = 0.71
\]

It is explained 0.71 percent of short-time changes of dependent variable by independent variable in this estimated equation, and term coefficient of error correction shows that it is
corrected 0.69 percent of lack of balance in next period in each one and modification is toward long-term.
