Abstract: A study was carried out to determine the prevalence of abomasal nematodes of sheep and goats slaughtered in Tabriz town from January 2012 through June 2012 with special emphasis given to Haemonchus species. During the study period 200 abomasas of sheep and 200 abomasas of goats were examined according to standard procedures. Three genera of nematodes were identified in both sheep and goats abomasas with overall prevalence of 88 % (n = 200). And 79.5 % (n = 200), respectively. The specific prevalence rates observed were 77.2 % for Haemonchus spp., 44.1% for Trichostrongylus axei, and 16.3% for Teladorsagia spp. in sheep and 73.1 % for Haemonchus spp., 36.2 % for T. axei and 17.3% for Teladorsagia spp. in goats. Generally a high infection rate with abomasal nematodes was observed in both sheep and goats of the study area. [Garedaghi Yagoob, Bahavarnia Seyed Razi. Seasonal prevalence of abomasal nematodes in small ruminants slaughtered at Tabriz town, Iran. Life Sci J 2013;10(5s):206-209] (ISSN:1097-8135).

Key words: prevalence, abomasal nematodes, Tabriz, sheep, goat.

1: Introduction
Sheep and goats, requiring little inputs, play vital role in rural economy through provision of meat, milk, blood, cash income, accumulating capital, fulfilling cultural obligations, manure, and contribute to the national economy through the export of live animals, meat and skins (Amenu, 2005). Helminth infections in domestic ruminants are of major importance in many agro-ecological zones in Iran and had the highest index as an animal health constraint to the poor keepers of livestock worldwide through losses due to reduced weight gains and growth rate, reduced nutrient utilization, lower meat, wool and milk production, involuntary culling, cost of treatment and mortality (Central Statistics Authority, 2004). Gastrointestinal nematodes are recognized as a major constraint to both small and large-scale small ruminant production in developing countries, leading to significant economic losses (Fritsche, 1993). The abomasal nematode Haemonchus contortus is particularly important and causes severe anaemia and death in severely infected animals (Hansen, 1994). Review of the available literature in Iran strongly suggests that helminthosis has nationwide distribution and is also considered as one of the major setbacks to livestock productivity incurring huge indirect and direct losses in the country. In Tabriz region livestock represent the pillar of the economy and plays a vital role in livelihood of the farming communities (Jacquet, 995). Of the endoparasites, the abomasal nematode H. contortus is incriminated as the dominant cause of parasitic gastroenteritis and exerts a severe economic toll in sheep and goats of Iran (Kreecek, 2006). On the contrary most studies on small ruminants for Tabriz region are scanty and unpublished and have basic limitations both in scope and coverage. Therefore comprehensive information on regional or national basis on this widely distributed, most pathogenic and economically very important abomasal nematodes such as H. contortus can be used as a baseline data to design sound helminth control strategy (Mulugeta, 1989). The present study was therefore aimed at determining the prevalence, species composition, and worm burden of abomasal nematodes of small ruminants of Tabriz region in Iran.

2: Materials and Methods
2.1. Study animals and design
The study was conducted on sheep and goats slaughtered in industrial slaughterhouse in Tabriz town from January 2012 through June 2012. Most of the study animals were originated from Tabriz and different areas of Tabriz town. Regular visits to slaughterhouse in Tabriz town allowed collections of abomasas of sheep and goats weight 30-45 kg and 1-5 year old for the study. As soon as possible, after removal of the alimentary tract from the body cavity, the abomasas ligated at both ends were cut and transported to the parasitology laboratory of Veterinary Medicine College in Tabriz branch, Islamic Azad University for microscopic examination.

2.2. Worm recovery, identification and count
Worm recovery, species identification and determination of worm burden were carried out according to standard procedures described by Hansen and Perry (1994) and MAFF (Ministry of Agriculture, Fisheries and Food) (1977). The abomasas were ligated at both ends and removed from omasum and duodenum. Then they were opened along the greater...
curvature and their contents were thoroughly washed in to a graduated bucket under a slow jet of water (the approximate volume of the abomasal content was 0.75 l). The mucus membrane was carefully rubbed with fingers to remove any worms adhering to it. The contents and washings were made to a total volume of two liters. Then it was vigorously stirred until all the abomasal contents, mucous and water were thoroughly mixed. A total of 200 ml of the contents was then transferred to a measuring cylinder in five steps of 40 ml per step while stirring the mixture. A sub-sample of 20 ml was transferred to a small graduated beaker to which 2 – 3 ml iodine was added to stain the worm and 2 – 3 ml sodium thiosulfate solution was also added to decolorize debris. Finally about 3 – 4 ml of the sample was placed in a Petri dish having parallel lines marked at 5 mm apart, diluted with water and examined under a stereomicroscope. Samples were examined for the presence of nematodes, which were identified and counted as male or female. The total number of worms counted in the 20 ml sub-sample was then multiplied by 100 to get the total number of worms present in the abomasums.

2.3. Statistical analysis
Descriptive statistics were used to summarize the data. In addition, Microsoft Excel software was used to store the data of abomasal nematodes. The software program, Stata, (intercooled Stata 7.5) and SPSS 11.5 were employed for data analysis.

3. Results
Examination of 200 abomasas of sheep revealed the presence of three different genera of nematodes with overall prevalence rates of 88 % (n = 176). The different genera identified were: Haemonchus 77.2 %, T. axei 44.1 % and Teladorsagia 16.3 % (Table 1). Likewise, of the total 200 abomasas of goats examined three genera of nematodes with overall prevalence rate of 79.5 % (n = 159) were recorded. The three genera of nematodes identified were: Haemonchus 73.1 %, T. axei 36.2 % and Teladorsagia 17.3 % (Table 2).

The overall monthly average worm burden ranged from 1740.1 in January to 2394.1 in March for sheep whereas it varied from 1650.2 in May to 2215.1 in January for goats. In sheep the highest Haemonchus count was recorded in April (777.1) and the lowest in February (628.2) and falls between these values for other months as shown in Table 1. The highest T. axei burden was recorded in March (992.2) and the lowest in January (550), while for Teladorsagia the highest worm burden was found in March (792.7) while the lowest was observed in February (450). In goats the average worm count for Haemonchus spp. was highest in January (720) and lowest in April (564.3), for T. axei the highest count was recorded in January (971) and lowest in May (503.8), where as the highest count for Teladorsagia was observed in April (625) and the lowest in June (550) as shown in Table 2. Generally sheep with 1953.2 overall mean worm count were found to be more heavily infested than goats with 1882.3 overall mean worm count during the study period. However, there was no statistically significant (P < 0.05) difference between months and host species in prevalence and worm burden of abomasal nematodes. Worm burden for haemonchus spp.(783±2), T.ax(w)I(524±1), Teladorsagia spp.( 431±3) in sheep and haemonchus spp.(559±6), T.ax(w)(488±1), Teladorsagia spp.( 393±4) in goats was calculated in this study. Also ODDS RATIO was in sheep (Young 2.7; Adult, Female 3.4 and Male 3.1) and in goats (Young 1.99; Adult, Female 2.87; Male 2.2).

Prevalence rate of abomasal nematodes in old animals (sheep and goat with 3-5 year aged) was 10-12 % further than young animals (1-2 year aged) also prevalence rate of abomasal nematodes in female sheep's and goats was 6-7% further than male animals. Also we don't find any Association of prevalence with nutritional status and breed category of sheep and goats in this study.

4. Discussion

The high overall prevalence and worm load of abomasal nematodes encountered in the current study is in agreement with the results of previous studies (El-Azazy, 1995) carried out his study in Saudi Arabia, which is a desert where hot dry climatic conditions prevail, whereas the present study was conducted in relatively wet and humid climate with variable amount of rain occurring during all months of the study period in Tabriz and its surrounding in Northwest of Iran. The results of worm counts presented herein showed slightly different patterns in sheep and goats. In sheep both the overall worm count and the specific counts for the three genera of nematodes showed similar trends. Even though the variation was insignificant, higher worm loads were recorded during March and April than January and February months of the study period. These higher worm counts during March and April coincide with the short rainy season in March to May in the area. This suggests that humidity and temperature during wet months favourably supports larval development and survival of nematodes in the pasture of the study area. In goats, the burden decreased from January onwards and then gradually started to rise in June. This difference between sheep and goats is most probably attributed to the difference in grazing habits and physiology of the two hosts (Thomas, 2007). In both sheep and goats Haemonchus spp. with respective prevalence of 77.2 % and 73.1 % was identified as the most predominant abomasal nematode of the area. This suggests the widespread occurrence of Haemonchus spp. In the area and, owing to its known high pathogenic significance, it can undoubtedly contribute to subtle production losses, unthriftness, morbidity and mortality of small ruminants of the study area (Tesfalem, 1989). In support of our results earlier investigators reported that Haemonchus constitutes the largest proportion of abomasal nematodes. Similar high prevalence rates of Haemonchus was observed by Bersissa (2004, 2006) in Ogaden (90.1 %), Dereje (1992) in Wollayita Sodo (80 %), Gennene (1994) in Kombolcha (83.9 %), Getachew (1998) in Mekele (95.4 %), Githigia et al. (2001), Wang et al. (2006) and El-Azazy (1995). The result of this study revealed that there was no significant (P < 0.05) difference in monthly infection rates of small ruminants by abomasal nematodes. This suggests the presence of infection during all months of the study period, which is in line with the observations of Bersissa (2006) and Tekelye (1987) who reported the occurrence of infection by abomasal nematodes throughout all seasons of the year in this study. Prevalence rate of abomasal nematode in old animals (sheep and goat with 3-5 year aged) was 10-12 % further than young animals (1-2 year aged). Also prevalence rate of abomasal nematodes in female sheep's and goats was 6-7% further than male animals. Also we don't find any Association of prevalence with nutritional status and breed category of sheep and goats in this study. In this study, moderate prevalence rates of T. axei (44.1 % and 36.2 %) and Teladorsagia spp., (16.3% and 17.3%) in sheep and goats, respectively were recorded. The result of this study is in support of the reports made by the previous workers. Even though its prevalence was lower than that of Haemonchus and T. axei, the importance of these parasites on the health and productivity of small ruminants should not be overlooked as the immature stages of these parasites are highly pathogenic to their host (Dunn, 1978). Moreover, this nematode has developed resistance to the most commonly used anthelmintics (Scott et al., 2007) and it has become a challenge to small ruminant production.

5. Conclusion

This study showed that small ruminants of the study area were found to suffer from high overall and monthly prevalence of abomasal nematodes infection. In both host species abomasal nematodes (especially Haemonchus spp.) are important impediments to small ruminant production of the area. The result of the present study revealed that sheep and goats in the study area are affected by similar prevalence and pattern of abomasal nematodes. Further investigation on biology of Haemonchus spp. and epidemiological studies to determine the associated losses in domestic
