Abstract In this paper, we present a three-step method of tenth order for determining multiple roots of a nonlinear equation. This method requires six evaluations per iteration, three evaluations of function and three evaluations of first derivative. Numerical examples are tested to compare our method with some other methods in the literature. We observe that our method is either comparable or has better performance in some cases than the other methods and preserves the order of convergence.

Keywords: Nonlinear equation, Multiple roots, Iterative methods, Modified Newton’s Method, Order of convergence.

1. Introduction

One of the most important and interesting problem in the field of numerical analysis, engineering, optimization theory and applied mathematics is determining the multiple roots of a nonlinear equation. A function \( g(x) \) is said to have a multiple root of a non-linear equation

\[ g(x) = 0, \]  

iff \( g(x) \) can be written as

\[ g(x) = (x - \alpha)^m h(x), \]

where \( \lim_{x \to \alpha} h(x) \neq 0 \) and \( m \) is the known multiplicity.

The modified Newton’s method (E.Schroder, 1870) is the most popular method for finding multiple roots of a nonlinear equation and is given as :

\[ x_{n+1} = x_n - m g(x_n) g'(x_n) \]  

This method has second order of convergence. In recent years, many variants of modified Newton’s method (N. A. Mir and Naila Rafiq 2007 and Li, et al 2010, ) have been developed and analyzed by using various techniques, which have either equal or improved order of convergence, efficiency and show better performance than the Newton’s methods

2. The Iterative Method

Thukral (2010) proposed a third order convergent method for finding multiple roots of non-linear equation:

\[ \begin{align*}
  y_n &= x_n - g'(x_n) g(x_n) \\
  x_{n+1} &= x_n - \frac{u g(x_n)^3}{g'(x_n)[g(x_n) - u g'(x_n)]^2}, \\
  \end{align*} \]

where \( u = (m-1)^n \), \( v = m^{n-1}, n \in \mathbb{N}. \)  

Li, et. al. (2010) developed fourth order method given as:

\[ \begin{align*}
  y_n &= x_n - \frac{2n}{n+2} \frac{g(x_n)}{g'(x_n)}, \\
  z_n &= x_n - 2 \left( \frac{m}{g(x_n)} \right) \frac{g'(x_n)}{g''(x_n)}, \\
  x_{n+1} &= x_n - \frac{2n}{n+2} \frac{g(x_n)}{g'(x_n)}, \\
  \end{align*} \]  

where

\[ a_1 = \frac{m^4 - 14m^3 + 12m^2 + 48m - 80m + 32}{8m(m^2 - 8m + 4)}, \]

\[ a_2 = \frac{-m}{16} \left( 3m^3 - 6m^2 - 20m + 40m - 16 \right), \]

\[ a_3 = \frac{1}{16} \left( m^3 - 4m \right), \]

\[ a_4 = \frac{m}{m - 2}. \]

Thukral (2012) proposed a fifth order convergent method:

\[ \begin{align*}
  y_n &= x_n - m \frac{g(x_n)}{g'(x_n)}, \\
  x_{n+1} &= y_n - m(1 + z^2) \frac{g'(x_n)}{g''(x_n)}, \\
  \end{align*} \]  

where \( z = g(x_n) g'(x_n)^{-1}. \)

Thukral (2010) proposed a three-step method:

\[ \begin{align*}
  y_n &= x_n - m \frac{g(x_n)}{g'(x_n)}, \\
  z_n &= y_n - mp \left( \frac{m}{1 - m} \right) \frac{g(x_n)}{g'(x_n)}, \\
  x_{n+1} &= z_n - m \left( u(p)^{1/2} + \left( \frac{g(x_n)}{g'(x_n)} \right)^2 \right)^{1/2} \frac{u(g'(x_n))}{u(g(x_n))} \left( \frac{g'(x_n)}{g(x_n)} \right)^{1/2}, \\
  \end{align*} \]  

where

\[ u(p) = 5 - 2b - (2 - 2b + 2b^2)p^2 + (1 + 4b)p, \]

\[ u(p) = \frac{5 - 2b - (2 - 2b + 2b^2)p^2 + (1 + 4b)p}{2 (2 - 2b + 2b^2)p + (1 + 4b)} \]

\[ p = g(x_n) g'(x_n)^{-1}. \]
This method has eighth order of convergence. We suggest the following three-step method for finding multiple roots which is the modification of the method (2.3) for multiple roots and is given as:

\[
y_n = x_n - m \frac{g''(x_n)}{g'(x_n)},
\]

\[
z_n = y_n - m(1 + \frac{b_m}{m}) \frac{g'''(x_n)}{g'(x_n)},
\]

\[
x_{n+1} = z_n - m(1 + \frac{3}{m}) \frac{g''(x_n)}{g'(x_n)},
\]

where \( a = g(x_0)g(x_1)^{-1} \) and \( h = g(z_0)g(x_1)^{-1} \).

3. Convergence Analysis

Now, we prove a theorem for finding the order of convergence of method (2.5).

Theorem: Let \( t \) be the multiple root of a nonlinear equation (1.1) with multiplicity \( m \), where the function \( g(x) \) is sufficiently differentiable in an open interval \( I=(a,b) \). Let \( x_0 \) be an initial guess sufficiently close to \( t \). Then the method (2.5) has tenth order of convergence and its error equation is given by:

\[ e_{n+1} = \left[ \frac{c_1}{m} + 4 \frac{c_2}{m} + 6 \frac{c_3}{m} - 12 \frac{c_4}{m} - 4 \frac{c_5}{m} + 9 \frac{c_6}{m} \right] e_n^m + o(e_n^m). \]

Proof:

Let \( e_n = x_n - t \). Using the Taylor expansion of \( g(x_n), g'(x_n) \) about \( t \), we get:

\[ g(x_n) \approx \left[ 1 + c_1 e_n + c_2 e_n^2 + \ldots \right], \]

\[ g'(x_n) \approx \left[ 1 + \frac{m+1}{m} c_1 e_n + \left( \frac{m+2}{m} c_2 + \ldots \right) e_n^2 \right], \]

where \( c_i = \frac{g^{(i)}(t)}{(i-1)!} \), \( k = 1,2, \ldots \).

Putting the values of \( g(x_n) \) and \( g'(x_n) \) in (2.5) and after simplification, we have:

\[ y_n = t + \frac{c_1}{m} e_n + o(e_n^2). \]

Also

\[ g(y_n) = 1 + \frac{c_1}{m} e_n + \left( \frac{2c_1 c_2}{m} - \frac{c_1}{m} \right) e_n^2 + o(e_n^2), \]

\[ g'(y_n) = 1 + \left( \frac{c_1}{m} + 2 \frac{c_2}{m} \right) e_n + \left( \frac{2c_1 c_3}{m^2} + 2c_2 c_2 + \frac{2c_2 c_3}{m} \right) e_n^2 + o(e_n^2). \]

Now, putting the values of \( y_n \), \( g(y_n) \) and \( g'(y_n) \) in (2.5), we have:

\[ z_n = t + \frac{3c_1}{m} e_n + \left( \frac{3c_1 c_2}{m} - \frac{c_1}{m} \right) e_n^2 + o(e_n^2). \]

Again, by Taylor expansion, we get:

Finally, putting the values of \( z_n \), \( g(z_n) \) and \( g'(z_n) \) in (2.5) and after simplification, we have

\[ x_{n+1} = t + \frac{c_1}{m} e_n + \left( \frac{4c_2}{m} + 6 \frac{c_3}{m} - 12 \frac{c_4}{m} - 4 \frac{c_5}{m} + 9 \frac{c_6}{m} \right) e_n^m + o(e_n^m), \]

or

\[ e_{n+1} = \left[ \frac{c_1}{m} + 4 \frac{c_2}{m} + 6 \frac{c_3}{m} - 12 \frac{c_4}{m} - 4 \frac{c_5}{m} + 9 \frac{c_6}{m} \right] e_n^m + o(e_n^m), \]

which shows that the method defined in (2.5) has tenth order of convergence.

4. Comparison of Method (2.5)

Here, we take some numerical examples from Thukral (2012) and compare our method with some other methods in the literature. The test functions, their roots and their initial guesses are displayed in Table 1, while Table 2 shows the absolute error \( |x_n - t| \) for each method. Each method is compared on their roots and their initial guesses in Table 1, while Table 2 shows the absolute error \( |x_n - t| \) for each method. Each method is compared on fourth iteration taking the following stopping criterion:

\[ |x_n - t| < \varepsilon, \]

where \( \varepsilon = 10^{-100} \).

All the computations reported here are done using 1000 significant digits. MNM represents Modified Newton’s Method, BNM represents Li’s method of fourth order given in (2.2) and NM represents the new method defined in (2.5). We can observe that the present method is well behaved.

**Conclusions**

In this paper, we proposed a new method, namely NM (2.5) for finding multiple roots of a nonlinear equation. We discussed the convergence analysis of new method and proved that this method has tenth order. At the end, we compared our method with some other methods. We observed that our method is comparable with other methods or has better performance than the other existing methods given in the Tables 2 and 4.
